

OBSERVATIONS OF COMETS AT THE SKALNATÉ PLESO OBSERVATORY, 1946—1963

Abstract: 586 accurate positions of 62 comets obtained at the Skalnaté Pleso Observatory in 1946—1963 are given, together with a list of reference stars and dependences. The methods of observation, measurement and reduction are briefly explained.

1. Methods of Observation and Measurement

Since the foundation of the Skalnaté Pleso Observatory, photographic observations of comets have been one of the regular programs of its 60 cm Zeiss parabolic reflector. During the period 1946—1963 altogether 62 comets were photographed in the Newtonian focus of the telescope ($f = 329$ cm) to obtain accurate positions. Occasionally, smaller instruments were used for photographing the comets as well.

The difficulties of guiding the diffuse cometary images accurately enough during longer exposures have been removed since 1948 by the construction of an auxiliary device for independent motion of the plate holder. This device permits guiding on a star in the neighbourhood of the comet, and following the comet's proper motion—as far as an ephemeris is available—by the orientation of the plate holder in the direction required and operation of a switch at regular time intervals. Each push displaces the plate holder by 0.016 mm = $1''$; the appropriate frequency of the pushes is either controlled acoustically, using a metronome, or an assistant observer is in charge of the operation of the device. This method of guiding substantially improved the quality of the images to be measured, and extended the magnitude limit accessible to the telescope. Making use of it, A. Mrkos succeeded in recovering three periodic comets at about $18''$.

Until 1953 no special apparatus for measuring the positions was available at the observatory and the measurements were carried out either with the Prin's measuring engine at the Astronomical Institute of the Czechoslovak Academy of Sciences in Prague or directly at the observatory by improvised means. The improvisation consisted in measuring the distances between individual reference stars and between the reference stars and the comet, either using a small Zeiss microscope with one micrometric screw or directly on a screen, in projection by a magnifying apparatus. Such measurements were rather troublesome and lengthy because of many repetitions (usually 10 for each distance) necessary in order to avoid too large random errors in reading. As close reference stars as possible were needed for this procedure. In 1953 a precise apparatus for measuring rectangular co-ordinates (Zeiss Koordinatenmessgerät 1) was acquired by the observatory and the measurements became much quicker and also more accurate.

Due to the comparatively small usable field of view of the parabolic mirror the application of the star catalogues of highest precision, with proper motions included, was usually impossible, and the positions had mostly to be referred to the Astrographic Zone Catalogues of CdC. In order to reduce the random errors due to the inaccuracy of the positions of the reference stars—in particular due to the unknown proper motions accumulated over several decades—it was customary to select as faint

reference stars as possible and to determine the position from six stars combined into two independent triangles. In those cases where the discrepancy between the two results was considerable (about 3" or more) efforts were made to identify and discard the stars with rapid proper motions by forming other combinations of stars into reference triangles and comparing the results. In some cases the proper motions according to special catalogues (Yale, EBL, Boss G.C., Geschichte des Fixsternhimmels) were applied to the positions from Astrographic Catalogues.

The reductions of the measurements were carried out by Schlesinger's method of dependences. The dependences were computed from rectangular co-ordinates using Prin's or Zeiss measuring apparatus; during the earlier work—in those cases where only distance measurements were available—they were computed from the triangle areas obtained by applying the Heron formula. From the comparison of some of the positions with accurate ephemerides it may be inferred that the probable error of position is generally not greater than $\pm 1''$ in each co-ordinate. For especially ill-defined objects without marked central condensation or nucleus it may reach $\pm 2''$ and even more.

Some of the positions have already been printed in the I.A.U. Circulars and used for the determinations of preliminary orbits, others have not yet been published anywhere. Nevertheless, as the wider use of electronic computers will be likely to lead to the re-determination and improvement of many orbits, it was felt desirable to repeat in the present list also the positions published earlier, with an accuracy increased from $0''.1$, $1''$ to $0''.01$, $0''.1$ and supplemented with the data on the reference stars and dependences.

2. Results of Computations

The positions of comets, arranged according to their definitive designations, are given in Table I. The first column of the table gives the serial number of observation of each comet, the next columns the middle of exposure in U.T., right ascension and declination for the equinox of 1950.0, the duration of the exposure (t), and the

abbreviations of the observers and computers respectively (Obs. = observation, M+R = measurement and reduction). Under the same serial number, Table II lists the reference catalogue, zone and plate number together with the reference star numbers and their dependences. In a few cases, where the original records were not available, these data are missing, but the plates are in the files of the observatory and may be remeasured if required. To provide information on the internal consistency of the measurements and the probable accuracy of the results, the differences between the two position determinations (from two independent triangles) $\Delta\alpha \cos \delta$ and $\Delta\delta$ are tabulated in the last two columns. In those cases where three or four triangles have been used, the averages of all mutual differences are given instead. In the remarks appended to the table some additional particulars are noted, e.g. the use of another telescope than the 60 cm reflector, the application of proper motions from another source than the reference catalogue etc.

The reduction constants of the Skalnaté Pleso Observatory are as follows:

$$\begin{aligned}\lambda &= 1^{\text{h}}20^{\text{m}}58^{\text{s}}77 \text{ E}, \\ \varphi &= 49^{\circ}11'20''0 \text{ N}, \\ h &= 1783 \text{ m above sea-level}, \\ \varrho &= 0.99836 \text{ earth equatorial radii.}\end{aligned}$$

The observatory Lomnický Štit, where some of the plates were taken by A. Mrkos, lies at a distance of less than 2 km from Skalnaté Pleso; hence the differences are generally immaterial for computing the parallax factors.

Table III presents an index of comets the positions of which are listed in Table I. For each comet under observation it gives the definitive and provisional designation, the name, and the total number of positions measured.

It must be emphasized that the present paper summarizes the results of a collective work of the Skalnaté Pleso Observatory staff. The share of individual collaborators, who took part in the comet programme during the past 18 years, is seen from Table IV. Our sincere thanks are due to all of them; the able assistance of Mrs. L. Ďurkovičová was helpful in preparing the tables for the manuscript.

Notes to Table II

- a — parabolic reflector 24/120 cm,
- b — Maksutov camera 34/44/95 cm,
- c — parabolic reflector 40/200 cm — Observatory Lomnický Štit,
- d — parabolic reflector 20/95 cm — Observatory Lomnický Štit,
- e — Maksutov camera 34/44/95 cm — Observatory Lomnický Štit,
- f — recovery observation,
- g — first photographic observation after discovery,
- h — measurement difficult — images of bad quality,
- i — measurement difficult—comet image crossed by a star trail
- j — comet image extremely faint,
- k — comet image extremely faint—identity uncertain,
- l — reductions less accurate—reference stars unfavourably situated,
- m — reductions less accurate—reference star positions discordant,
- n — reference star numbers according to BD, zone 48°,
- o — referred to only one star in close vicinity,
- p — proper motions of stars No. 806, 808, 838, 858 from Yale
- q — p.m. from EBL,
- r — p.m. of No. 3977 and 3986 from Yale,
- s — p.m. of No. 293 from Boss GC,
- t — p.m. of No. 11 and 39 from Geschichte d. Fsh.,
- u — p.m. of No. 2350 from Boss GC,
- v — p.m. of No. 2938 and 3145 from Boss GC,
- w — p.m. from Boss GC,
- x — p.m. of No. 3386 from Boss GC,
- y — p.m. of No. 66 from Geschichte d. Fsh.,
- z — p.m. of No. 31664 and 31728 from Yale.

(For the reference star positions from Yale Zone Catalogue and Cape Catalogue proper motions are *always* included.)

НАБЛЮДЕНИЯ КОМЕТ НА ОБСЕРВАТОРИИ СКАЛЬНАТЕ ПЛЕСО В ПЕРИОД 1946—1963 ГГ.

Фотографические наблюдения положений комет входят в постоянную программу обсерватории Скальнате Плесо с самого ее основания. В связи с современной программой поисков комет в ряде случаев удалось получить первые фотографии новых комет и фотографии, которые были использованы для определения первых орбит.

Для фотографических наблюдений используется основной телескоп обсерватории — 60-ти сантиметровый рефлектор Цейсса в Ньютонской установке. В качестве более точного гидирования телескопа и фотографирования более слабых, в ведущей трубе уже не видимых движущихся объектов, кассетная часть тефлектора снабжена устройством для передвижения фотопластинки в любом позиционном направлении; движение кометы элиминировано гидировкой на звезду с одновременным передвижением пластинки по эфемериде по $1''$. Фотопластинки измеряются на прямоугольном измерительном приборе Цейсса „Комес 1“; для обработки применялся метод зависимостей Шлезингера. Небольшое поле параболического рефлектора в большинстве случаев не позволяет сравнивать комету со звездами с известным собственным

движением. Поэтому используются преимущественно опорные звезды Астрографических каталогов.

Ошибки каталога, а также происходящие из различия эпохи ошибки уничтожены избранием двух треугольников, составленных из самых слабых по возможности звезд. Приведенные в табл. II для каждого положения различия пар независимых определений экваториальных координат, представляют некоторые информации о точности результатов. Этот контроль и сравнение больших серий положений с точными эфемеридами показывают, что вероятная ошибка результата, как правило, меньше чем $1''$ для любой координаты. Только в случаях, когда комета очень слаба, без явной центральной конденсации или же без ядра, вероятная ошибка достигает $\pm 2''$.

В сводных табл. I, и II. приведены результаты этой программы, полученные в период 1946—1963 гг., в общем 586 положений 62 комет, список которых приведен в табл. III. Работа является результатом труда большого числа сотрудников; список сотрудников и данные об их участии в наблюдениях, измерениях и обработке, приведен в табл. IV.

L. KRESÁK — M. ANTAL

POZOROVANIA KOMÉT NA OBSERVATÓRIU NA SKALNATOM PLĒSE V ROKOCH 1946 — 1963

Pozičné fotografovanie komét je jedným zo stálych programov observatória na Skalnatom Plese už od jeho založenia. V spojitosti so súčasným programom hľadania komét podarilo sa v rade prípadov získať prvé snímky nových komét a snímky, ktoré poslúžili pri výpočte prvých dráh.

Na fotografické sledovanie sa používa hlavný dalekohľad observatória — 60 cm Zeissov reflektor v Newtonovom usporiadaní. Pre spresnenie vedenia dalekohľadu a fotografovanie slabých pohyblivých objektov, neviditeľných v pointovacom refraktore, je kazetová časť reflektoru doplnená zariadením na posun platne v lubovoľnom pozičnom uhle; pohyb komety sa eliminuje pointovaním na hviezdu so súčasným posunom platne podľa efemeridy po $1''$. Snímky sa premeriavajú na Zeissovom prístroji na meranie pravouhlých súradníc Komess 1 a merania sa redukujú Schlesingerovou metódou dependencií. Malé pole parabolického reflektora väčšinou nedovoľuje premeriavať kométu ku hviezdam so známym vlastným pohybom. Najčastejšie sa preto používajú referenčné hviezdy

z Astrografických katalógov CdC, pričom chyby katalógu a chyby z rozdielov v epoche sa obmedzujú výberom dvoch trojuholníkov, zložených z čo najslabších hviezd. Rozdiely z dvoch neodvislých určení ekvatoreálnych súradníc, uvedené pre každú polohu v tabuľke II, podávajú určitú informáciu o presnosti výsledkov. Táto kontrola spolu s porovnaním väčších sérií polôh s presnými efemeridami ukazuje, že pravdepodobná chyba výsledku je pravidelne menšia ako $1''$ v každej súradnici. Iba v prípadoch, keď je kométa veľmi slabá, bez zreteľnej centrálnej kondenzácie alebo jadra, dosahuje pravdepodobná chyba hodnotu $\pm 2''$.

V tabuľkách I a II podávame súhrnné výsledky tohto programu za roky 1946—1963, celkove 586 polôh 62 komét, ktorých zoznam je uvedený v tabuľke III. Práca je kolektívny výsledkom väčšieho počtu spolupracovníkov; ich zoznam, s uvedením podielu na pozorovaniach, meraniach a redukciách, podáva tabuľka IV.
