

# Spectral modeling of flares on AD Leo

Authors:

Mgr. Jiří Wollmann, prof. RNDr. Petr Heinzel, DrSc.

In collaboration with:

Dr. Petr Kabáth, Mgr. Magdaléna Špoková,  
Dr. Raine Karjalainen

# Outline

1. Introduction
  - ▶ Solar flares
  - ▶ Stellar flares
2. Model
  - ▶ Setup
  - ▶ Results and comparison
3. Conclusions
4. Future work

# Introduction - solar flares

- ▶ sudden brightenings on the solar surface
- ▶ energy is released due to magnetic reconnection
- ▶ typical time-scale tens of minutes to hours
- ▶ phases:
  - ▶ pre-flare
  - ▶ impulse
  - ▶ gradual

# Introduction - stellar flares

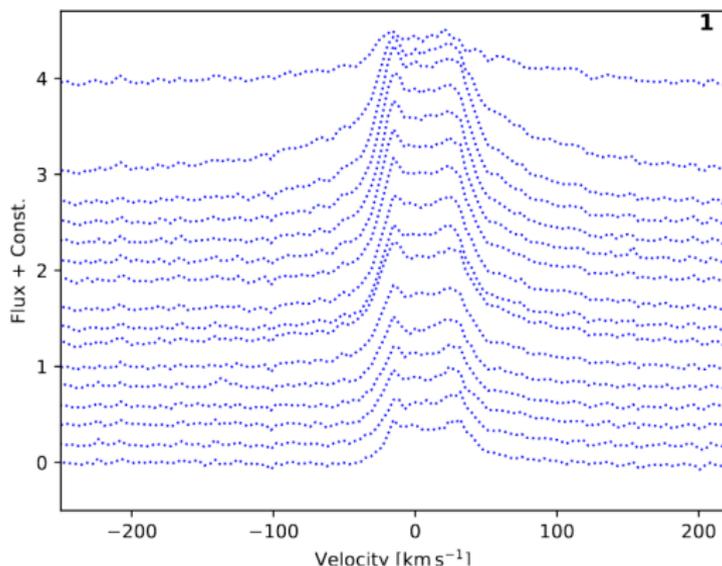

- ▶ most common on K and M stars
- ▶ compared to Sun they tend to have vast and strong magnetic fields
- ▶ energy released during solar flares -  $10^{28} - 10^{32}$  erg
- ▶ energy released during typical stellar flares on M stars  $10^{31} - 10^{34}$  erg (super-flares up to  $10^{36}$  erg)

# Introduction - stellar flares - why study them

- ▶ expand our knowledge of processes in stellar atmospheres
- ▶ every other M type star has a planet in habitable zone (Tuomi et al., 2019)
- ▶ flares affect planet's habitability, especially their atmosphere

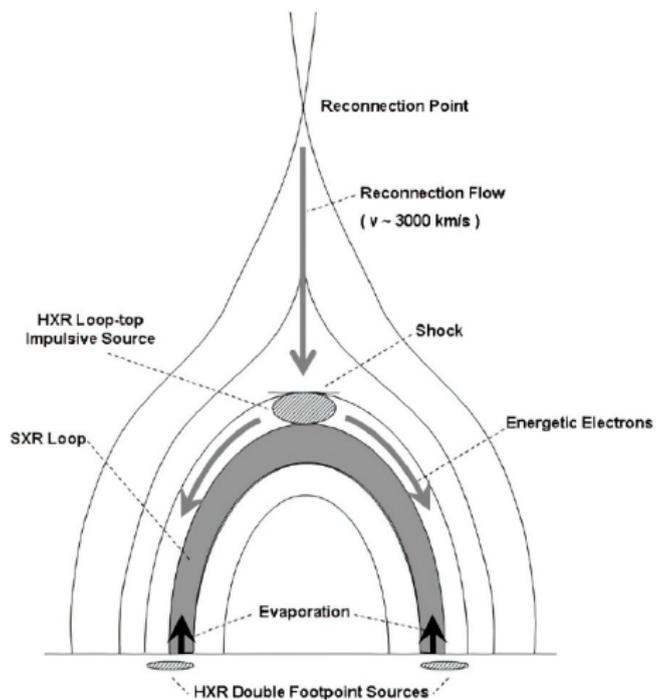

# Introduction - stellar flares - spectral line asymmetries

- ▶ some spectral lines show asymmetrical profile compared to the rest profile during flares - origin is not well understood
- ▶ we assume they are caused by chromospheric flows of plasma

Source: Muheki et al. (2020)

# Introduction - solar flares - standard model

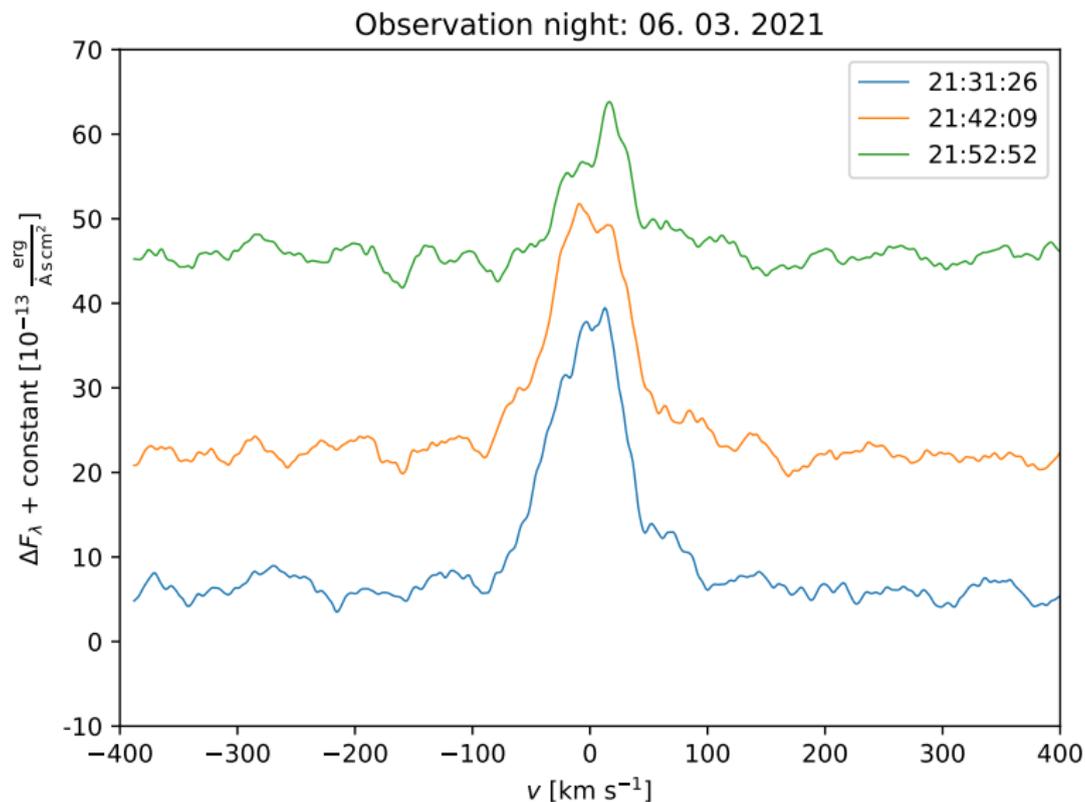

# Introduction - solar flares

- ▶ video - coronal rain

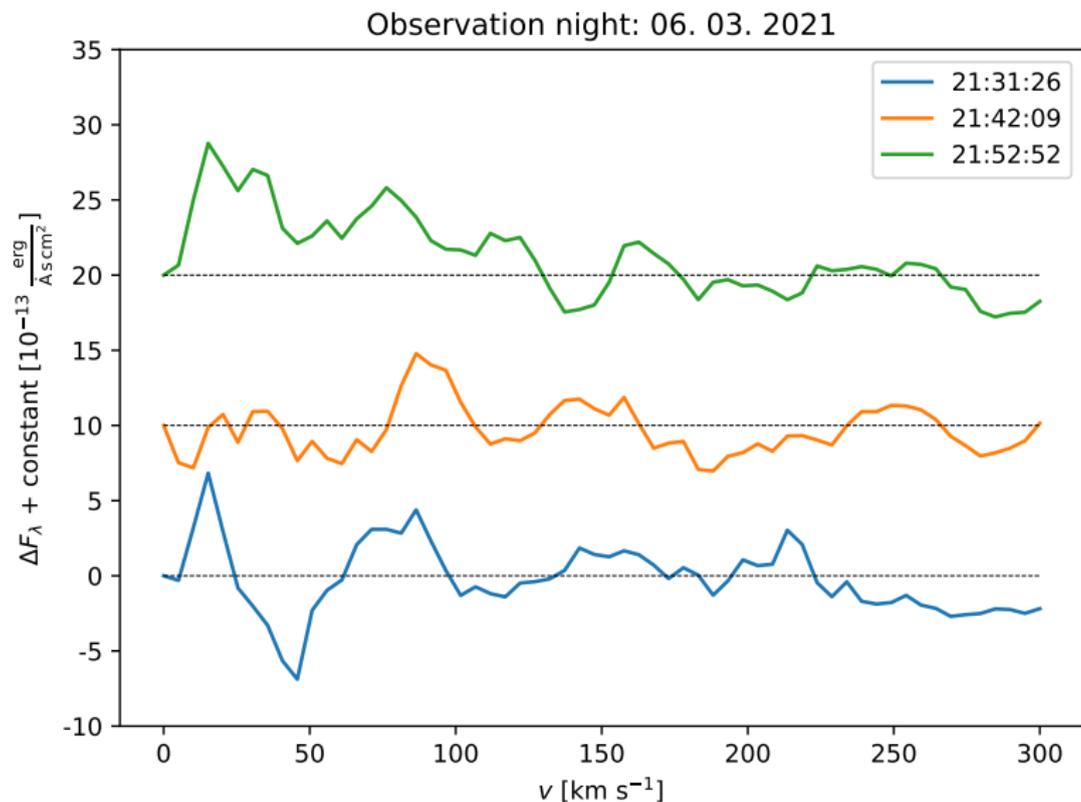

## Observations - AD Leo

- ▶ spectral type dM3.5eV
- ▶  $m \approx 0.4 M_{\odot}$
- ▶ frequently studied star
- ▶ statistically a flare occurs once every two hours
- ▶ spectra in visible region with exposure time 10 - 15 minute using 2m Perek telescope in Ondřejov

# Observations - H $\alpha$ profile changes

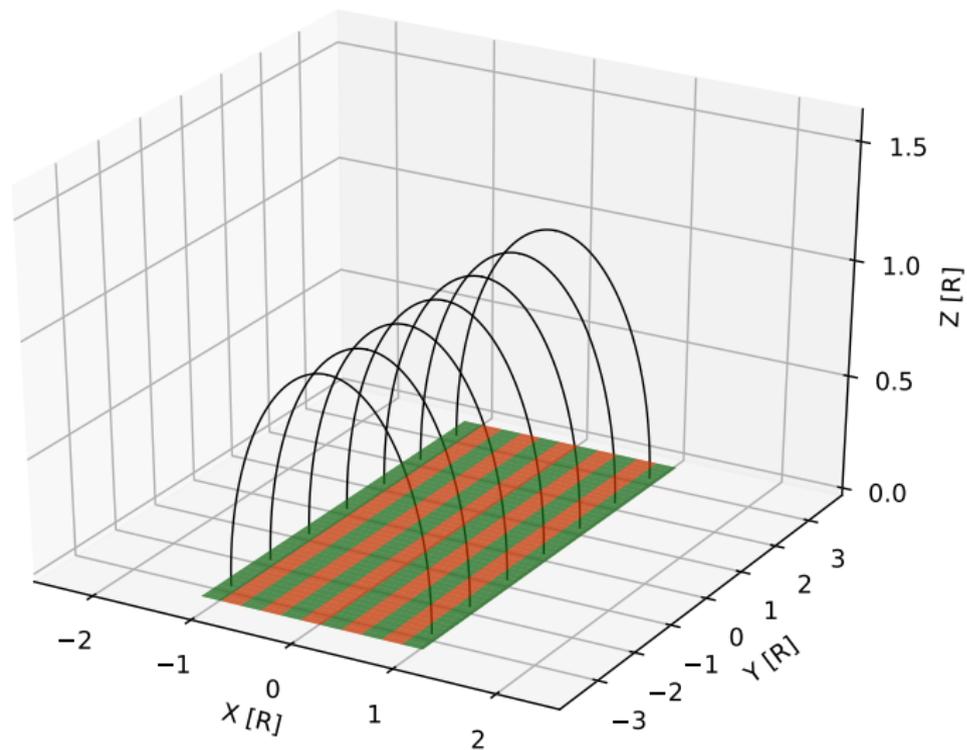

# Observations - H $\alpha$ profile changes

## Model - Setup

- ▶ aims to probe origin of asymmetry of spectral lines profiles
- ▶ current implementation solves  $H\alpha$  line
- ▶ solution of radiation transfer through flare loops using approximation of cloud model
- ▶ clouds move along circular loops
- ▶ flare occurs at the stellar disc center with respect to the observer

# Model - Setup

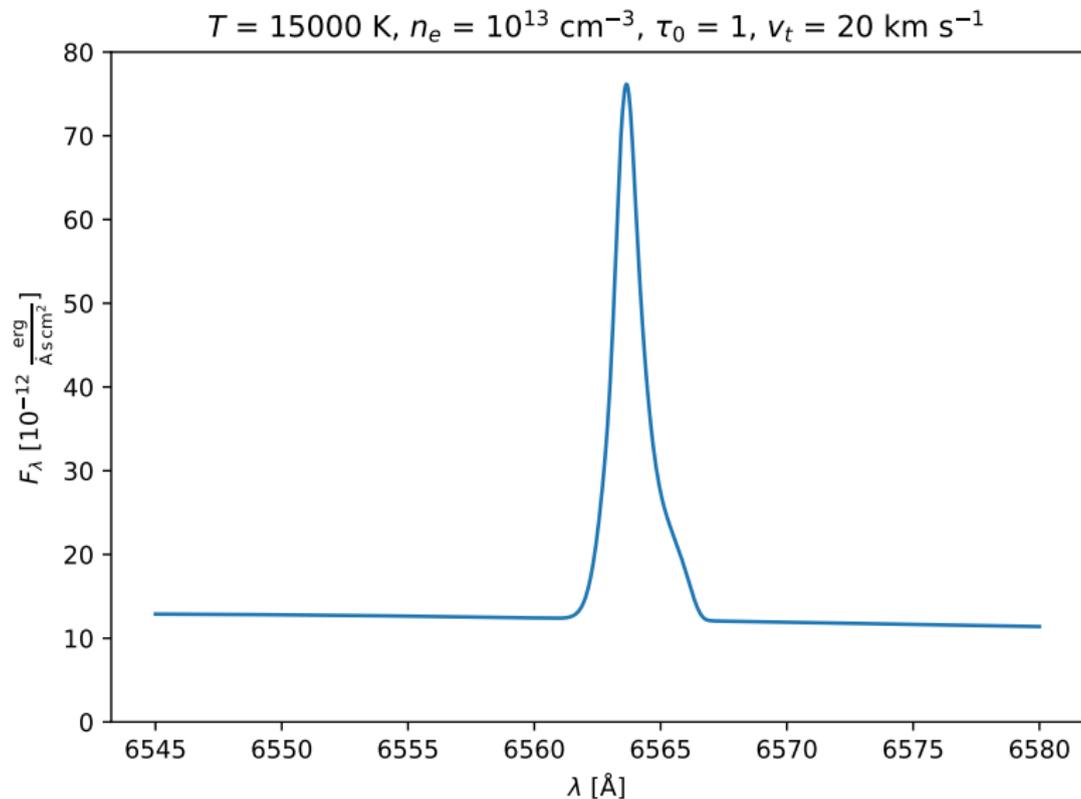

## Model - Setup - specific intensity

- ▶ approximation of two-level atom and constant source function through a single cloud
- ▶  $S = \epsilon B(\lambda_0) + (1 - \epsilon)\bar{J}$
- ▶ source function depends on velocity of cloud with respect to the stellar surface
- ▶  $I_\lambda(0) = I_\lambda(\tau_\lambda)e^{-\tau_\lambda} + S(v)(1 - e^{-\tau_\lambda})$
- ▶ parameters: temperature, optical thickness, electron density, radius of circular loop, turbulent velocity

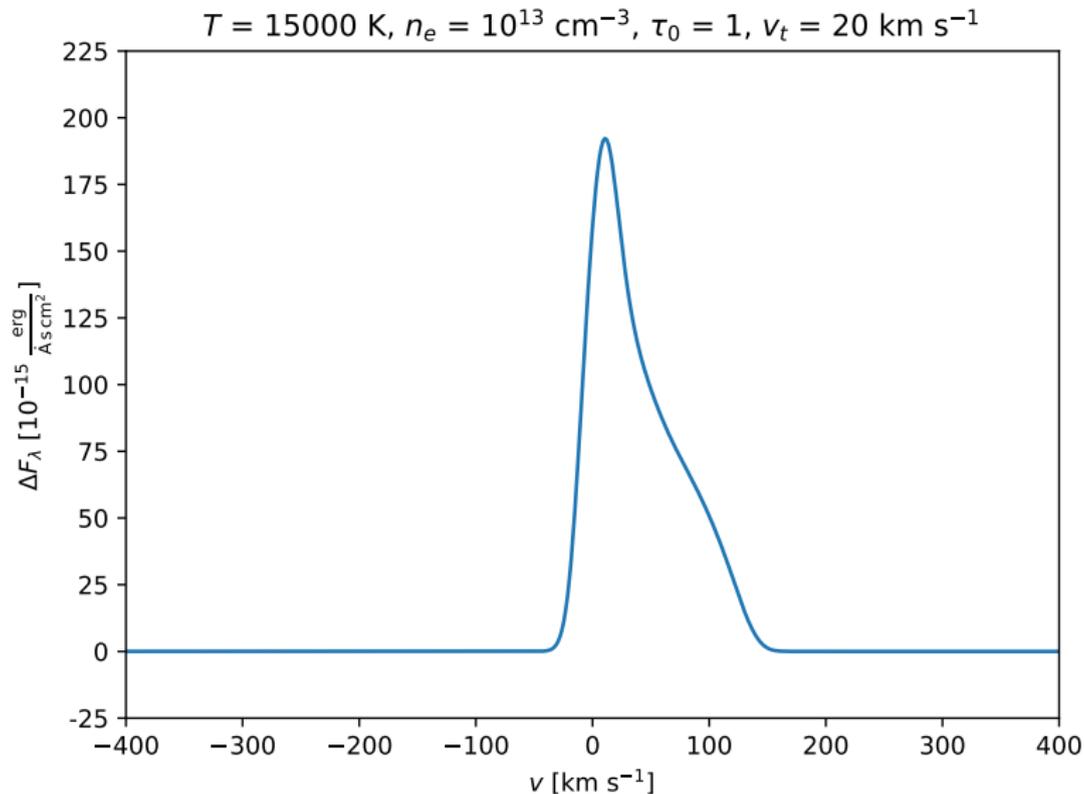

# Model - Preliminary results - single cloud spectrum

▶ video

# Model - Preliminary results - spectrum of flare arcade

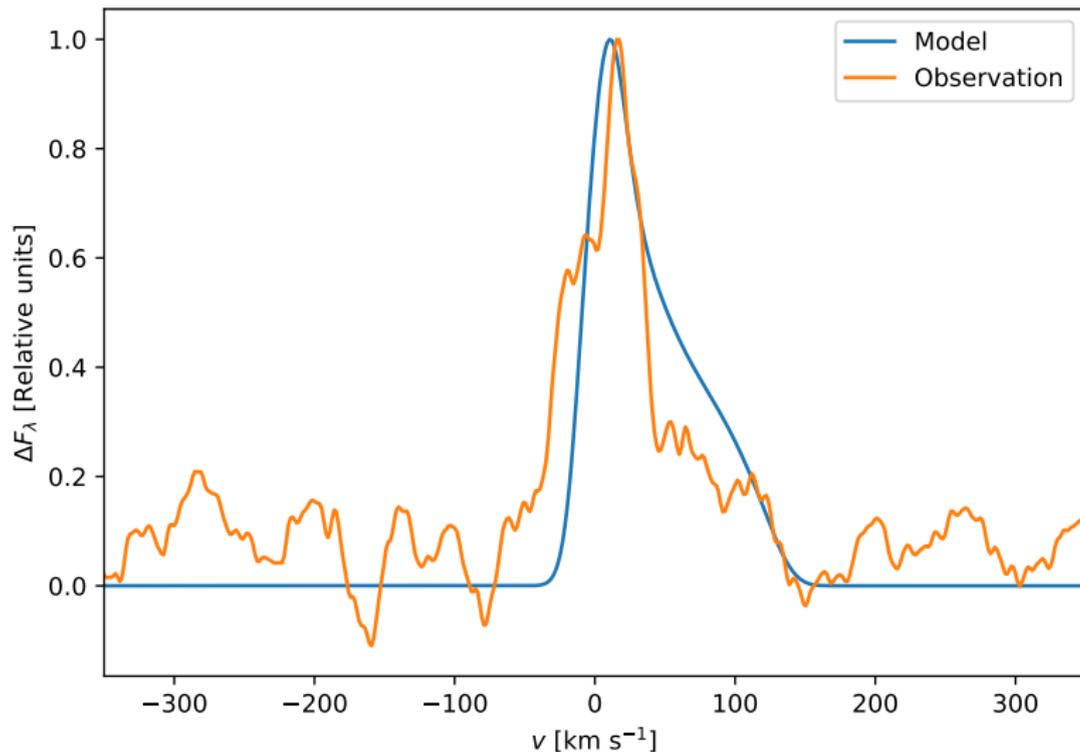

# Model - Preliminary results - flare spectral line effect

# Model - Comparison with observations

$T = 15000 \text{ K}$ ,  $n_e = 10^{13} \text{ cm}^{-3}$ ,  $\tau_0 = 1$ ,  $v_t = 20 \text{ km s}^{-1}$

# Conclusions

- ▶ we observed asymmetrical profiles of  $H\alpha$
- ▶ simple model of radiation of circular flare loops yields asymmetrical profile that matches *some* observations

## Future work

- ▶ simulate synthetic spectra using RHD code Flarix
- ▶ generalise location of flare on the stellar disc with respect to the observer
- ▶ use more robust methods of plasma motion simulation along flare loops
