Received 2 October 1987

ABSTRACT. The results of observations of prominences made at the Lomnický Štít coronal station in the years 1967-1986 are reported. The position, area in relative units, latitudinal extent and relative brightness of each prominence are given. Some results of the statistical treatment (distribution of the number and areas of prominences, as well as the N-S asymmetry) are also reported. Preferred heliographic longitudes in the occurrence of prominences as well as their differentiated evolution towards the poles in the course of the cycle were observed in both cycles and both hemispheres at intermediate and high heliographic latitudes. Prominence areas between minimum and maximum of the solar activity changed in the ratio of about 1:2, number of prominences of 1:3.

КАТАЛОГ СОЛНЕЧНЫХ ПРОТУБЕРАНЦЕВ (1967-1986 гг.). В статье опубликованы результаты наблюдений протуберанцев на корональной станции Ломницкий Штит за 1967-1986 гг. Для каждого протуберанца приведены: положение, площадь в относительных единицах, ширина в основании и яркость в трех-балльной шкале. Приведены тоже некоторые результаты статистической обработки материала (распределение числа, площадей протуберанцев и асимметрия в северо-южном направлении). В обоих циклах, на обоих полусферах, в средних и высоких широтах наблюдались долготы в которых появлялись протуберанцы преимущественно и тоже разное пове-

дение этих зон во время цикла в направлении к полюсам. Площадь протуберанцев изменяется от минимума к максимуму цикла в отношении 1:2, их число в отношении 1:3.

KATALOG SLNEČNÝCH PROTUBERANCIÍ (1967-1986). V článku publikujeme výsledky pozorování protuberancií na koronální stanici Lomnický Štít v letech 1967-1986. Pro každou protuberanciu uvádíme její polohu, plochu v relativních jednotkách, délku protuberancie při povrchu Slunce a relativní jas. Dále uvádíme některé výsledky statistického zpracování (rozdělení počtu a ploch protuberancií jako aj severo-júžnú asymetriu). V oboch cykloch na oboch pólguľiach v stredných a vysokých heliografických šírkach sa vo výskyte protuberancií pozorovali preferované dĺžky ako aj ich diferencovaný vývoj smerom k pólu. Plocha protuberancií medzi minimom a maximom slnečnej aktivity sa menila v pomere okolo 1:2, počet protuberancií v pomere okolo 1:3.

1. INTRODUCTION

Prominences (Figure 1) are dense, cool clouds of hydrogen plasma in the solar corona which, according to Babcock and Babcock (1955), "form in the line of demarcation between photospheric fields of opposite polarity". Their observations above the limb or as projections on the solar disk (in this case called "filaments") provide valuable information not only of the large-scale topology

Figure 1: Solar prominences taken at Lomnický Štít coronal station in H-alpha.

of the solar magnetic field, e.g. (Makarov and Sivaraman, 1985), but also about the dynamics of displacement of neutral lines from heliographic mid-latitudes towards the poles at speeds ranging from 4.2 to 8.5 m s^{-1} . The problem of the distribution of prominences over the solar disk remains unsolved. Wolfer (1897) was the first to determine qualitatively the active or preferred longitudes of prominences within one cycle. His study disclosed the existence of two high latitude preferred longitudes at a mutual distance of approximately 180° . Hansen and Hansen (1975) and Menzel and Bell (1953) drew attention to filament clastering, the former in cycle 20, the latter in earlier cycles. Finally, also the preliminary analysis of cycles 20 and 21 (Rušin et al., 1986) indicated the preferred longitudes in both of these cycles. Prominences are located in the solar corona, but little is known of mass transfer between them; Lebecq (1988) pointed out, using observations of high resolution, that part of the coronal matter could come from prominences (an opposite process is observed more frequently). The reader is reminded that the mass of one large prominence is comparable with the mass of the whole corona.

The paper presents a summary of prominence observations made at the Lomnický Štít coronal station in the years 1967-1986 (i.e. nearly over two solar cycles), as well as some of the results of their statistical treatment (N-S asymmetry, distribution of prominences in heliographic latitude and longitude, total number and area of prominences in the course of cycles 20 and 21). Some of the statistical data (height, width, occurrence within the cycles) were already published earlier (Rušin et al. 1986).

2. OBSERVATIONS AND DATA-PROCESSING

The regular photographic observations of prominences at Lomnický Štít have been made with a coronagraph, the 20-cm diameter of a lens and with H-alpha filter (FWHM = 0.8 nm) since 1967 (May). Between 100 and 140 of observation days are available for each year since 1967.

The basic processing of the photographic material was carried out at Lomnický Štít, i. e. the heliographic latitude, area of prominences in terms of the "vertical" area of 1° in heliographic longitude and $10''$ in geocentric height, the height (in arcsec) and width (in degrees) and relative brightness of prominences was determined on a three-degree scale.

This basic material was then further processed in the Department of Astronomy and the National Observatory (DANO) at Sofia. The heliographic longitude and the ordinal number of Carrington's rotation were determined for each prominence. The results are given in Table 1 which forms the actual "Catalogue of Prominences". The symbols marking the individual columns in the Table 1 are: NO-ordinal number of the prominence, Y-year, M-month, D-day, ROT-rotation, L-heliographic longitude, B-heliographic latitude, X-length of prominence (in degrees at the solar surface), H-height of the prominence (in arcsec), I-brightness of the prominence (a subjective estimate derived from a film density), A-area of the prominence (degree x arcsec).

Since this "Catalogue" has also been recorded on magnetic tape, we give its following characteristics: EBCDI code on 9-track tape of density 800 bpi, BLOCKSIZE = 4800 bytes, RECORD SIZE = 48 bytes, No. of RECORDS = 16 620. For convenience purposes, to facilitate the distribution and use, in near future it will be recorded in the FITS format in compliance with the requirements of IAU.

3. RESULTS AND DISCUSSION

As mentioned in the Introduction, the basis for the further study of prominences are the data in Table 1.

The distribution of the prominences in heliographic longitude and latitude is shown in Figures 2-21 (Lambert's projection; N-denotes number of prominences observed in each half-year and hemisphere). These Figures clearly show the existence of preferred longitudes at mid- and high heliographic latitudes, whose evolution can be observed from their beginning in 1977 to their decay at the poles in 1980 in the northern hemisphere and 1981 in the southern hemisphere (incomplete evolution can also be observed in the years 1967-1970).

In 1977, one can observe a number of local areas with increased numbers of prominences at latitudes 40° - 50° which formed four very bright preferred regions at latitudes 50° - 60° one year later. They are not exactly mutually at a distance of 90° . In the next year, only two preferred longitudes existed, spaced at 180° . These preferred longitude in cycle 21 were located at heliographic longitudes 0° and 180° , in cycle 20 at 30° and 210° . Just before they reached the poles, the well-known "polar crown" was observed. The distribution of the prominences relative to the pole in this period was not symmetrical, nor did the maximum itself lie precisely on the poles (see Figures 4, 5, 15, 16). The reason for this anomaly appears to be related to the preferred longitudes observed 2-3 years earlier at lower latitudes. Besides this, the displacement of the maxima at the individual preferred longitudes of the polar zone appears to be affected by differential rotation.

There are preferred longitudes also in the neighbourhood of the equator, but not all of them will be mentioned due to their numbers. Moreover, they can not be observed over a longer period as in the case of the preferred longitudes at mid- and high latitudes, which is due to their different evolution.

In 1980, a conspicuous decrease (Figure 15) in the number of prominences was observed at heliographic longitudes of 150° to 210° in the neighbourhood of the southern pole. A decrease in the brightness of the white-light corona was observed at roughly the same heliographic longitudes during the solar eclipse on February 16, 1980 (Rušin and Rybanský, 1983). In our opinion, this fact is evidence of a close relation with the mass transfer between prominences and the corona or vice versa.

An interesting situation occurred in the southern hemisphere in 1982, a year after the disintegration of the polar prominence zone. A new zone of polar prominences (Figure 17), which was not observed the year after, began to form at heliographic latitudes of 50° - 60° . A similar pattern was also observed in

Figure 2: Lambert's projection of prominences for 1967. N-denotes a number of prominences in all next Figures. A basic isoline has value 3 and each next is made by the step 2. This is valid for all the next Figures.

1970, but in the northern hemisphere (Figure 5). In both the years mentioned, a conspicuous increase in the coronal index of the green corona was observed (Rybanský and Rušin, 1988), which may indicate a certain degree of correlation. This correlation could be due to the emergence of new magnetic field from below the photosphere, or it could be connected with the changes in a rotation rate of the corona as derived from coronal index (Rušin et al., 1988). Changes in the rotation rate of the green corona were indeed observed in both cases. However, some problem is that, in the other cases of changes of rotational rates, no so conspicuous changes are observed in the prominences, even when they exist. Usually, prominence areas are rising if rotational rates, as derived from semi-annual data sets of the coronal index, are changed.

The latitudinal distribution of the number of prominences separately for the northern and southern hemispheres is shown in Table 2 and Table 3. A similar distribution of prominence areas is given in Table 4 and Table 5. Both sets of Tables clearly indicate the displacement of the high latitude prominence zones towards the poles, as in other cycles, e.g. Makarov and Sivaraman (1985).

The time distribution of prominence areas separately for the northern and southern hemispheres, and also for both together, is shown in Table 6, Table 7 and Table 8. The monthly average areas are plotted in Figure 22. The average annual values of areas are plotted in Figure 23 (there are the Wolf's number given for a comparison) and indicate that the ratio of the average minimum and maximum values is about 1:2 (cycle 20, 1:1.89; cycle 21, 1:1.86). The number of prominences between minimum and maximum of a cycle varied in the ratio of about 1:3. It does not appear as if the prominence areas in the maximum depended on Wolf's number. Although the values of Wolf's number were higher in cycle 21 than in cycle 20, a lower average values of areas were observed, but

Figure 23: Yearly means of number and prominence areas (Wolf's number for a comparison).

on the other hand, high average values of areas were observed over a longer period, although the opposite was true between the cycles.

The N-S asymmetry has been observed in all manifestations of solar activity over a large number of years, e.g. Waldmeier (1957). The magnitude of the asymmetry is defined by the relation $A=(N-S)/(N+S)$ for the areas and number of prominences, and is shown in Table 9. The asymmetry of prominence areas is plotted in Figure 24. For comparison we showed the asymmetry of the green corona

Figure 24: The north-south asymmetry of prominence areas (dotted line) and in the green corona (full line) in the years 1965-1986.

Table 9

The asymmetry of prominence areas and numbers

in 1964-1986. As one can see no preference for any hemisphere is observed in either phenomenon, as in the years 1959-1967 (maximum in 1965) when solar activity was observed particularly in the northern hemisphere (Waldmeier, 1971 and others. In both cases, the alternating values of asymmetry continued from 1969 to 1986, and varied between $A = \pm 0.30$. It can not be determined unambiguously on what this depends, or during which period one or the other hemisphere predominates. Consequently, no definitive explanation of the asymmetry in the manifestations of solar activity can be given at this time.

ACKNOWLEDGMENTS

The authors express their gratitude to Dr M. Kopecký of the Astronomical Institute of the Czechoslovak Academy of Sciences for the useful comments of this manuscript and to K. Maník and L. Scheirich for the basic processing of the material and for preparing the Figures.
